

## FIRST REPORT OF *DUCHESNEA INDICA* F. *ALBOCAPUT* (ROSACEAE) IN NORTHWESTERN ARGENTINA

MARIO A. DEBES<sup>1,2 \*</sup>, INGRID G. ORCE<sup>3</sup>, ANA C. LUQUE<sup>1</sup>, JUAN C. DÍAZ-RICCI<sup>2</sup>, ATILIO P. CASTAGNARO<sup>3</sup> and MARTA E. ARIAS<sup>1,4</sup>

**Summary:** The genus *Duchesnea* includes two species originally from India: *D. indica* and *D. chrysanthia*. In Northwestern Argentina the monitoring of wild strawberry-like species was carried out; during 2002-2016, many populations of *D. indica* and none of *D. chrysanthia* were discovered. Red- and white-fruited plants of *D. indica* were collected from disturbed areas and *ex situ* conserved in green-house and in nursery conditions. Were also consulted materials from different national and international herbaria, and we only found reports of *D. indica* with red fruit for Argentina. In the present work, we report for the first time the presence of *D. indica* f. *albocaput* in Argentina and South America, cohabiting with populations of *D. indica* f. *indica* in the underwoods of Tucumán. This finding broadens the distribution range of *D. indica* f. *albocaput*, cited as endemic to Japan by Naruhashi 1992. The morphological and anatomical characters of the two botanical forms of *D. indica* (red fruit genotypes and white fruit genotypes) are also presented: fruit color, number of leaflets, and crystal form.

**Key words:** *Duchesnea*, morpho-anatomical, wild-strawberry.

**Resumen:** Primer informe de *Duchesnea indica* f. *albocaput* (Rosaceae) en Noroeste de Argentina. El género *Duchesnea* incluye dos especies originarias de India: *D. indica* y *D. chrysanthia*. Durante el período 2002-2016, se realizaron monitoreos de especies silvestres relacionadas con la frutilla cultivada en el Noroeste Argentino y se encontraron numerosas poblaciones de *D. indica* pero ninguna de *D. chrysanthia*. Plantas de *D. indica* con frutos rojos y plantas con frutos blancos fueron colectadas y conservadas *ex situ*, en cámaras bajo condiciones controladas y en invernaderos a campo. Se consultaron también materiales de diferentes herbarios nacionales e internacionales, y solo se encontraron reportes de ejemplares de *D. indica* de frutos rojos para Argentina. En el presente trabajo se reporta por primera vez para Argentina y Sudamérica, la presencia de poblaciones de *D. indica* f. *albocaput*, co-habituando con poblaciones de *D. indica* f. *indica* en sotobosques de Tucumán. Con esta cita se amplía el rango de distribución de *D. indica* f. *albocaput*, citada como endémica para Japón. Se presentan además, las características morfo-anatómicas distintivas de ambas formas botánicas de *D. indica* (genotipos de frutos rojos y genotipos de frutos blancos): color del fruto, número de foliolos, y forma de cristales.

**Palabras clave:** *Duchesnea*, frutillas silvestres, Morfo-anatomía.

## INTRODUCTION

The biodiversity of the Yungas eco-region is high; despite, demographic expansion, deforestation process and agricultural practices generated areas with endangered species or sensible to diversity-loss. Despite to the great process of transformation and degradation, the pre-montane forests in Northwestern Argentina have higher percentage of exclusive species and patches with good status of biodiversity conservation (Brown, 2009; Malizia *et al.*, 2012).

The genus *Duchesnea* includes two species native from India: *Duchesnea indica* and *Duchesnea chrysanthia*. *D. indica* is reported as ubiquitous from different regions of the world and cited as adventitious from Argentina (Zardini 1973, 1999, Arias 2007, Zuloaga, 2008). *D. chrysanthia* grows mainly in Japan, China, India, Korea, Taiwan, the Philippines, Indonesia, and it has not been reported in America (Kalkman, 1968; Sugimoto & Naruhashi, 1981; Kume *et al.*, 1987; Sugimoto *et al.*, 1991; Naruhashi, 1992; Naruhashi, 2001). Both species are very similar: plants in rosette, tri-foliated leaves, yellow flowers, runner producers and active ground colonizers (cespitoso) (Zardini, 1973, 1999; Novara, 1993; Arias 2007); fruits of *D. indica* are scarlet-red and larger than the pink-reddish fruits of *D. chrysanthia* (Naruhashi & Sugimoto, 1996). In both species, white-fruited genotypes have been reported: *D. chrysanthia* f. *leucocephala* (Makino) Hara (Naruhashi & Iwatsubo, 1991), from Korea, and *D. indica* f. *albocaput* Naruh. endemic in Honshu (Fukui Pref.), Japan (Naruhashi, 1992, 2001).

Anatomical comparisons among *D. indica*, *D. chrysanthia* and their hybrids were carried out by Naruhashi & Ishizu (1992). Arias (2007) reported foliar anatomical characters observed in two forms of *D. indica*. Cytological and genetic studies revealed the presence of five ploidy forms in *Duchesnea* from Gifu Prefecture (Japan),  $2n = 14, 21, 49, 56, 84$  with a basic haploid set  $x = 7$  (Iwatsubo & Naruhashi, 1991; Naruhashi & Iwatsubo, 1991). Plants with  $2n = 49$  (heptaploid) and  $2n = 56$  (octoploid) were considered as natural hybrids between *D. chrysanthia* ( $2n = 14$ ) and *D. indica* ( $2n = 84$ ) (Naruhashi & Takano 1987). One example is *D. x harakurosawae* N. Naruhashi & M. Sugimoto, a heptaploid ( $2n = 49$ ) hybrid

that despites being sterile, propagates actively by vegetative reproduction (Naruhashi & Sugimoto, 1996).

In this paper we report the presence of *D. indica* f. *albocaput* growing in low highland forests of Tucumán (Argentina). We also present the chromosome number and a comparative analysis of the morpho-anatomical characters between *D. indica* f. *albocaput* and *D. indica* f. *indica*.

## MATERIALS AND METHODS

### Study area and collecting sites

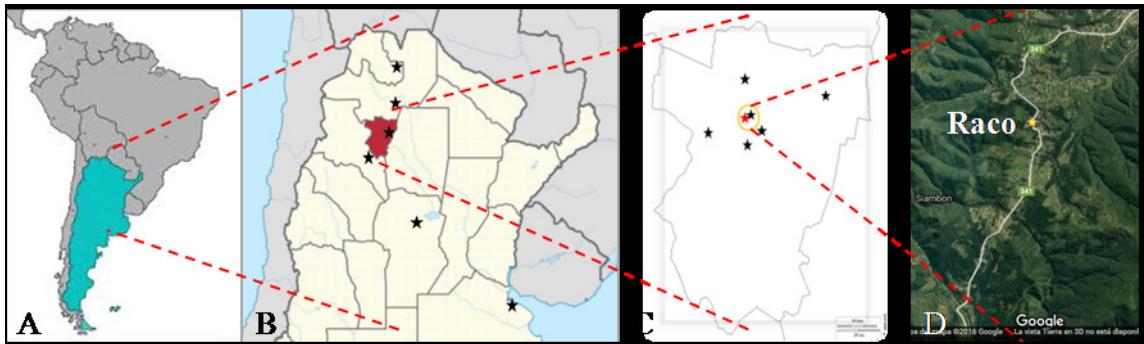

The presence of wild strawberries-like species in different sites of Northwestern Argentina was monitored during 2002-2016 at summer and winter seasons (Fig. 1A, B). Areas with different environmental conditions (mountain forests, highland pastures, and riparian habitat) were monitoring. *D. indica* genotypes from different sites were selected and collected for *ex situ* conserving in green-house of Banco de Germoplasma de Frutilla de la Universidad Nacional de Tucumán (BGF-UNT).

### Comparative analyses between red- and white-fruited plants

From *ex situ* conserved genotypes clones of both forms of *D. indica* were obtained by agamic propagation in BGF-UNT (by stolon rooting) for morphological analyses. Vegetative and reproductive traits were analyzed in different plants of successive propagations. Achenes germination in green-house was also evaluated.

Leaves of 15 red- and 15 white-fruited plants were collected and fixed in FAA (formalin-acetic acid-alcohol 80° (3:1:5)) (D' Ambrogio de Argüeso, 1986), and treated according conventional techniques (Dizeo de Strittmater, 1980; D' Ambrogio de Argüeso, 1986). Anatomical analysis with light microscope was made; in addition, polarized light microscope for crystals analysis was used.

Meiotic studies from young immature flowers of white- and red-fruited plants were performed; the samples were fixed in absolute alcohol and glacial acetic acid solution (3:1) during at least 12 hours at 4 °C. Immature anthers were squashed with a drop of propionic acid (45%), hematoxylin (2%);

**Fig. 1.** Geographical distribution of *Duchesnea indica* in South America. A, regional distribution in Argentine. B, reported sites in central and northwestern region. C, distribution in different Tucumán province localities. D, satelital image of Raco locality. Black star signaling occurrence of *D. indica* f. *indica*, and red star indicate presence of *D. indica* f. *albocalput*.

ferric citrate (1%) as a mordant were used (Nuñez, 1968). Cytological analyses using a minimum of 20 pollen mother cells in different meiotic stages were carried out; the chromosomal counting on diakinesis stage was only made.

#### Taxonomic treatment

Same plants collected were *ex situ* conserved (in green-house of BGF-UNT) and others, were herborized and deposited in the Herbarium of the Fundation Miguel Lillo (LIL). Different herbaria collections: La Plata (LP), Darwinion (SI), Museo de Ciencias Naturales de Salta (MCNS), Museo Botánico de Córdoba (CORD) and Herbario Miguel Lillo (LIL) were consulted. Additionally, digitals copies of white-fruited specimens from Makino Herbarium, Metropolitan Tokyo University (MAK) were also analyzed.

## RESULTS

***Duchesnea indica*** (Andrews) Focke, Nat. Pflanzenfam. 3 (3): 33. 1888.

*Potentilla grandiflora*, auct. non L., Thunb., Fl. Jap.: 219. 1784. *Fragaria indica* Andrews, Bot. Repos. 7 Tab. 479. 1807. Bot. 16(71): 666. 1908. *Duchesnea indica* (Andrews) Teschem. var. *major* Makino, Bot. Mag. Tokyo 28: 184. 1914. *Duchesnea major* (Makino) Makino, J. Jap. Bot. 2:19. 1921. *Duchesnea indica* Andrews, Fieldiana. Bot. 24 (4): 432-484. 1946.

Hirsute, perennial and stoloniferous herbs, with short rhizome (crown) often thickened; green runner with rooting nodes and caulinar tripartite stipules. Trifoliolated green opaque leaves, elliptic leaflets with margin serrate and long petioles with loosely pubescence (adpresous) and bipartite foliar stipules. Flowers perfect, solitary, axillary (on long peduncles arising from nodes), 5-merous; calyx and epicalyx persistent and green and slightly pubescent; petals 5, yellow, obovate early deciduous; numerous pistils sessile and

free. The styles are persistent in lateral position at the achenes. Stamens in several cicles. Fruiting receptacle scarlet-red, fleshy, insipid and edible. Achenes red, numerous, reniform and prominent (Fig. 2C and E).

**Duchesnea indica (Andrews) Focke f. albocaput**  
Naruh. J. Phytogeogr. Taxon. 40(2): 131. 1992.

**Typus. JAPAN. Honshu island, Chubu:** Fukui prefecture, Fukui city, Asuwa-sanzan, 21-VI-1991, Wakasugi 34420 (FR); ibidem, 24-X-1991, Wakasugi & Naruhashi 91102401 (FR); and, 10-VI-1991, Wakasugi & Naruhashi 92061001 (FR; HOLO-: KANA; ISO-: KYO, MAK, TI & TNS) not seen.

Perennial, stoloniferous herbs with crown often thickened; green runner with rooting nodes and caulinar tripartite stipules. Dark green leaves, trifoliolate and sometimes tetrafoliolate or pentafoliolate, leaflets obovate-elliptic with margin serrate; venation semicraspedodromous (scarcely branched secondary venation). Petiole long, with variable length (5-14cm), green and pubescence. Trichomes: glandular (with pluricellular, uniseriate foot and pluricellular head) and single (unicellular) in epidermis of petiole and leaf blade. Crystals: prismatic and cubic in the mesophyll of the leaf. Flowers axillary perfect (15-25mm diameter), solitary, 5-merous; calyx and epicalyx persistent and green; petals 5, yellow obovate-obcordate early deciduous; numerous pistils sessile and free. The styles are persistent in lateral position at the achenes. Stamens in several cicles. Fruiting receptacles flesh, convex, accrescent, insipid and edible; the fruiting receptacles white, with 60-120 cream achenes, prominent and reniform smoothly; in addition, slight changes in color-achenes of this genotypes were registered, to brown-cream and to cream-pinkish in spring. However, the new fruits of self-plants in others season return to typical cream color (Fig. 2 and 3).

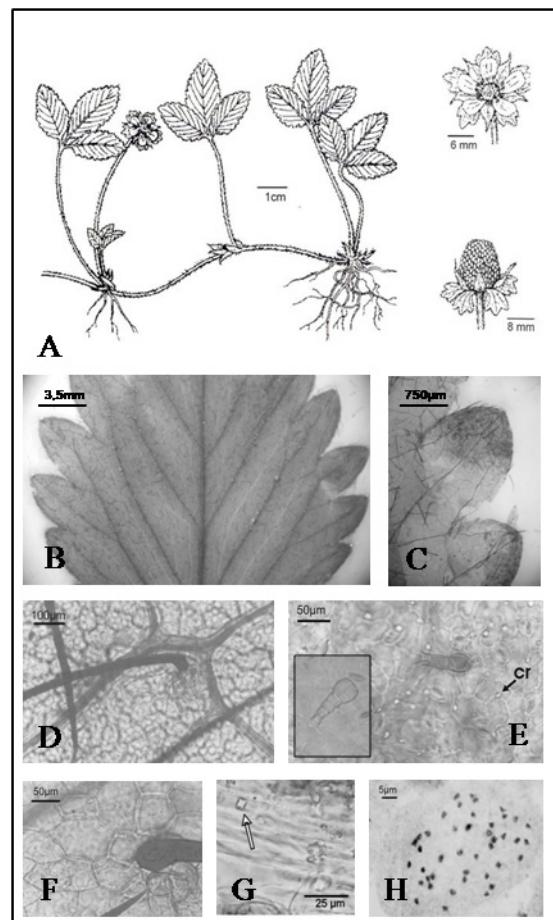

**Specimens examined. Tucumán:** Dpto. Tafi Viejo, Raco, 1.IX.2004, Arias & Gómez 601 (LIL).

#### Taxonomic considerations

According to species description, the Holotypus is housed in KANA and ISOTYPUS in KYO, MAK, TI & TNS (Naruhashi, 1992). After of an exhaustive search in those herbaria, we not found theses materials. Answering to this conflict, we considered that one NEOTYPUS is necessary for this taxon (International code of botanical nomenclature article 9.6).

#### Distribution of *Duchesnea* sp.

In highlands of Tucumán province, in Northwestern Argentina, plants of *D. indica* f. *albocaput* were found in 2004 (Fig. 1C, D). This particular white-fruited genotype, grow under pinewood co-habiting with red-fruited *D. indica* (Fig. 2A).

**Fig. 3.** Morphological and anatomical characters of *Duchesnea indica* f. *albocaput*. A, General aspect to plant with trifoliolate leaves, short crown with stolons leaves and axillary flower; details: flower and fruit. B, Aspect to venation pattern (secondary and tertiary veins). C, Marginal arrangement (semicraspedodromous). D, Simple trichoma. E, Glandular trichoma, arrow: cubic crystals. F, Epidermical-cells disposition in simple trichoma base of adaxial surface Simple trichoma. G, Foliar cross section with different crystals in parenchyma; the arrow indicates a cubic crystal. H, Meiotic chromosomes.

During more than 10 years of monitoring, many populations of *D. indica* f. *indica* (red-fruited) and only one population of *D. indica* f. *albocalput* (white-fruited) were found. However, none population of *D. chrysanthia* in different sites of this region was found.

#### *Comparative analyses between D. indica f. indica and D. indica f. albocalput*

The evaluation of vegetative and reproductive characters of both forms *ex situ* conserved, showing similar stolons number (average =10 ± 2) with 3-5 daughter plants by stolons; however, the number of clones obtained was minor in *D. indica* f. *albocalput* than the other form (Fig. 2B, C); foliar and others vegetative characteristics were summarized in Table 1. The number of flowers for plant in both form of *D. indica* were variable according to season (3-7) showing a peak in October (spring season); the fruiting receptacle production was also variable (3-5) depending on the season. The number of achenes by fruiting receptacle ranged from 60 to 120 (± 10) with major production in December (Fig. 2D, E).

On more than 10 years of evaluation in BGF-UNT, the color-fruit was a stable trait in all conserved genotypes: red fruit in *D. indica* f. *indica* and white fruit in *D. indica* f. *albocalput* (Fig. 2B, C). Nonetheless, slight changes in achene-color of *D. indica* f. *albocalput* at some seasons were observed. In summer instead of

cream color to brown-cream and cream color to pinkish-cream- in spring (Fig. 2F); however, red color in this botanical form was never observed.

The germination of achenes was successfully for all of genotypes of *D. indica*. However, the major percentage of germination was observed in red achenes of *D. indica* f. *indica* (95%) regard to cream achenes of *D. indica* f. *albocalput* (62%). The plantlets with good development and similar aspect to the mother plants were obtained in both forms.

Similar epidermal characters such as: isodiametric cells in adaxial epidermis and lobulated cells in abaxial epidermis, anomocytic stomata, glandular trichomes (with pluricellular head), single trichome (unicellular) in both botanical forms of *D. indica* were found. Spheroidal aggregate of prismatic crystals of calcium oxalate (druses) were observed in parenchyma cells of the mesophyll and in the middle bundle. However, distinctive characters such as: the epidermal cells disposition (in rosette or a group of prominent cells wrapping) on base of simple trichomes and type of calcium oxalate crystals inclusions (prismatic and cubic) in the mesophyll and the parenchymatic phloem cells were only found in white-fruited *D. indica* (Fig. 3B-E).

Cytological studies revealed that the white-fruited *D. indica* is dodecaploid ( $2n = 12x = 84$ ) as happens in the red-fruited genotype (Fig. 3F).

**Table 1.** Distinctive characters observed between red-fruited *D. indica* and white-fruited *D. indica*.

	<i>D. indica</i> f. <i>indica</i>	<i>D. indica</i> f. <i>albocalput</i>
Leaves	Trifoliate	Trifoliate and tetra-pentafoliate
Terminal leaflet length/width	2.5-3.7 x 1.6-2 cm	1.5-4 x 1.2-3 cm
Shape of leaflet	Elliptic	Elliptic, obovate-elliptic
Length of petiole	5-14 cm	8-16 cm
Achenes, color and position	Red, reniform, asymmetric superficial	Ochre, reniform asymmetric superficial with stile persistent
Transversal section of leaves	Vascular bundle of the medium nerve not prominent	Vascular bundle of the medium nerve prominent
Crystals in parenchyma of central bundle	Druses	Druses and prismatic or cubic crystals
Base of trichomes simple	With a rosette of cells in the base	Have either a rosette of basal cells or a group of prominent cells wrapping the base

## DISCUSSION

The several *D. indica* populations found in different areas confirmed the high plasticity of this species to colonize many places. The capacity of flowers and fruits production of white-fruited *D. indica* is similar to the red-fruited plants. However, slight differences in stolons rootings and percentage of achenes germination could explain the minor occurrence of white-fruited populations or a low capacity to colonize new lands regard to the red fruited plants.

The color fruit is an important characteristic to attract disperser agents. The red or white color of fruiting receptacle and achenes was the more conspicuous character that differences the two forms of *D. indica* analyzed in this work. Furthermore, few changes of achenes-color of white-fruited *D. indica* were observed seasonally but never in the red-fruited populations. Successful crosses between *D. indica* f. *indica* and *D. indica* f. *albocaput* in both directions and self-pollinations were carried out by Debes et al. (2011); those authors report compatibility between them and variations in color of fruiting-receptacle and achenes in offspring.

In vascular plants, anthocyanin and betacyanin pigments are wide distributed and their accumulations are involved in the red color of flowers and fruits (Shimada et al., 2004). According to Espley et al. (2009), the pigment biosynthesis in apple may be induced by light, particularly UV, and various stress treatments including cold. In addition, mutations in genes encoding for the biosynthetic or transcriptional regulators of the anthocyanin pathway have been linked to changes in color phenotypes (Espley et al., 2009). Molecular studies in red- and white-fruited *D. indica* reported that impaired in *ANS* gene expression is responsible of white color of fruits (Debes et al., 2011).

On other hand, the presence of small cubic and prismatic calcium oxalate crystals in leaves of *D. indica* f. *albocaput*, different of druses in leaves of *D. indica* f. *indica*, constitutes a new diagnostic trait not reported for *Duchesnea* genus. Factors involved in the crystals morphology regulation were studied by Nakata-Paul (2002); according to this research, the control of crystal morphology is a tightly regulated genetic process and a single

point mutation can drastically alter the crystals size and shape. From to this, and based on our anatomical observations, we can thought that the new local white-fruited *D. indica* here described, could be result from a single or a few *loci* point mutations that may have occurred in the normal red-fruited *D. indica* f. *indica*.

Conversely, we could speculate that the local white-fruit genotype is, in fact, a new botanical form originated from an independent spontaneous mutation event that took place in the ubiquitous local red-fruit *D. indica* f. *indica* affecting the fruit color locus. Is also probably, that the occurrence of this white-fruited genotype has been produced by a “Wright effect” from a small population of red-fruit *D. indica* (Naruhashi personal communication, 2011).

Taken together these results, we concluded that white-fruited *D. indica* found in Tucumán (Argentina) is *D. indica* f. *albocaput*. This discovery increases the knowledge about the diversity of the *Duchesnea* genus.

Regard to taxonomic considerations, we consider that in order to elucidate the conflict in question, a more profound taxonomy study should be carried out to establish, according to the international code of botanical nomenclature, a new reference material for this taxon; however, these aspect of this research exceeds the objectives of the present paper.

## ACKNOWLEDGEMENTS

This work was partially supported by the Consejo de Investigaciones de la Universidad Nacional de Tucumán (PIUNT D544/1); Agencia Nacional de Promoción Científica y Tecnológica, FonCyT (INTA-PICT 2011 N° 1170). IGO and MAD are fellows of CONICET. and ACL, is fellow of CIUNT. Authors wish to thank: Dr. N. Naruhashi at the Department of Biology - University of Toyama (Japan) for kindly providing achenes of *Duchesnea chrysanthia* f. *leucocephala*; Professor N. Murakami at the Makino Herbarium - Tokyo Metropolitan University (Japan) for digital images of *Duchesnea indica* var *leucocephala* Ing. Lemme, MC for technical assistance and Banco de Germoplasma de Frutilla de la Universidad Nacional de Tucumán (BGF-UNT) for providing plants and installations used.
